October 29, 2020

---

**ABSTRACT.** We describe a family of graphs with queue-number at most 4 but unbounded stack-number. This resolves open problems of Heath, Leighton and Rosenberg (1992) and Blankenship and Oporowski (1999).

---

## 1 Introduction

Stacks and queues are fundamental data structures in computer science, but which is more powerful? In 1992, Heath, Leighton and Rosenberg [12, 13] introduced an approach for answering this question by defining the graph parameters *stack-number* and *queue-number* (defined below), which respectively measure the power of stacks and queues for representing graphs. The following fundamental problems, implicit in [12, 13], were made explicit by Dujmović and Wood [8]<sup>1</sup>:

- Is stack-number bounded by queue-number?
- Is queue-number bounded by stack-number?

If stack-number is bounded by queue-number but queue-number is not bounded by stack-number, then stacks would be considered to be more powerful than queues. Similarly, if the converse holds, then queues would be considered to be more powerful than stacks. Despite extensive research on stack- and queue-numbers, these fundamental questions have remained unsolved.

We now formally define stack and queue layouts of graphs. Let  $G$  be a graph and let  $<$  be a total order on  $V(G)$ . Two disjoint edges  $vw, xy \in E(G)$  with  $v < w$  and  $x < y$  *cross* with respect to  $<$  if  $v < x < w < y$  or  $x < v < y < w$ , and *nest* with respect to  $<$  if  $v < x < y < w$  or  $x < v < w < y$ . Let  $\varphi : E(G) \rightarrow \{1, \dots, k\}$  for some integer  $k \geq 1$ . Then  $(<, \varphi)$  is a *k-stack layout* of  $G$  if, for every pair of edges  $vw, xy \in E(G)$ , if  $\varphi(vw) = \varphi(xy)$  then  $vw$  and  $xy$  do not cross. Similarly, the pair  $(<, \varphi)$  is a *k-queue layout* of  $G$  if, for every pair of edges

<sup>1</sup>A *graph parameter* is a function  $\alpha$  such that  $\alpha(G) \in \mathbb{R}$  for every graph  $G$ , such that  $\alpha(G_1) = \alpha(G_2)$  for all isomorphic graphs  $G_1$  and  $G_2$ . A graph parameter  $\alpha$  is *bounded* by a graph parameter  $\beta$  if there exists a function  $f$  such that for every graph  $G$  we have  $\alpha(G) \leq f(\beta(G))$ .

PM: Suggestion: Replace second if then with  $\varphi(vw) \neq \varphi(xy)$  or  $vw$  and  $xy$  do not cross.

---

$vw, xy \in E(G)$ , if  $\varphi(vw) = \varphi(xy)$  then  $vw$  and  $xy$  do not nest. The smallest integer  $s$  for which  $G$  has an  $s$ -stack layout is called the *stack-number* of  $G$ , denoted  $\text{sn}(G)$ . The smallest integer  $q$  for which  $G$  has a  $q$ -queue layout is called the *queue-number* of  $G$ , denoted  $\text{qn}(G)$ . Note that stack layouts are equivalent to book embeddings (first defined by Ollmann [15]), and stack-number is also known as *page-number*, *book-thickness* or *fixed outer-thickness*. See [1, 2, 5–7, 9, 14, 18, 19] and the references therein for work on stack- and queue-layouts.

Given a  $k$ -stack layout  $(\prec, \varphi)$  of a graph  $G$ , for each  $i \in \{1, \dots, k\}$ , the set  $\varphi^{-1}(i)$  behaves like a stack, in the sense that each edge  $vw \in \varphi^{-1}(i)$  with  $v \prec w$  corresponds to an element in a sequence of stack operations, such that if we traverse the vertices in the order of  $\prec$ , then  $vw$  is pushed onto the stack at  $v$  and popped off the stack at  $w$ . Similarly, each set  $\varphi^{-1}(i)$  in a queue layout behaves like a queue. In this way, the stack-number and queue-number respectively measure the power of stacks and queues to represent graphs.

### Is Stack-Number Bounded by Queue-number?

This paper considers the first of the above questions. In a positive direction, Heath et al. [12] showed that every 1-queue graph has a 2-stack layout. On the other hand, they described graphs that need exponentially more stacks than queues. In particular,  $n$ -vertex ternary hypercubes have queue-number  $O(\log n)$  and stack-number  $\Omega(n^{1/9-\epsilon})$  for any  $\epsilon > 0$ .

Our key contribution is the following theorem, which shows that stack-number is not bounded by queue-number. This demonstrates that stacks are not more powerful than queues for representing graphs.

**Theorem 1.** *For every  $s \in \mathbb{N}$  there exists a graph  $G$  with  $\text{qn}(G) \leq 4$  and  $\text{sn}(G) > s$ .*

The graph  $G$  in Theorem 1 is the cartesian product<sup>2</sup>  $S_b \square H_n$ , where  $S_b$  is the star graph with root  $r$  and  $b$  leaves, and  $H_n$  is the dual of the hexagonal grid, defined by  $V(H_n) := \{1, \dots, n\}^2$  and

$$\begin{aligned} E(H_n) := & \{(x, y)(x+1, y) : x \in \{1, \dots, n-1\}, y \in \{1, \dots, n\}\} \\ & \cup \{(x, y)(x, y+1) : x \in \{1, \dots, n\}, y \in \{1, \dots, n-1\}\} \\ & \cup \{(x, y)(x+1, y+1) : x, y \in \{1, \dots, n-1\}\} . \end{aligned}$$

The graph  $G$  in Theorem 1 is  $S_b \square H_n$  (see Figure 1), where  $b$  and  $n$  are chosen to be sufficiently large compared to  $s$ . Note that Pupyrev [16] independently suggested using graph products to show that stack-number is not bounded by queue-number.

### Subdivisions

A noteworthy consequence of Theorem 1 is that it resolves a conjecture of Blankenship and Oporowski [4]. A graph  $G'$  is a *subdivision* of a graph  $G$  if  $G'$  can be obtained from  $G$  by replacing the edges  $vw$  of  $G$  by internally disjoint paths  $P_{vw}$  with endpoints  $v$  and  $w$ . If each  $P_{vw}$  has exactly  $k$  internal vertices, then  $G'$  is the  $k$ -*subdivision* of  $G$ . If each  $P_{vw}$  has at

---

<sup>2</sup>For graphs  $G_1$  and  $G_2$ , the *cartesian product*  $G_1 \square G_2$  is the graph with vertex set  $\{(v_1, v_2) : v_1 \in V(G_1), v_2 \in V(G_2)\}$ , where  $(v_1, v_2)(w_1, w_2) \in E(G_1 \square G_2)$  if  $v_1 = w_1$  and  $v_2 w_2 \in E(G_2)$ , or  $v_1 w_1 \in E(G_1)$  and  $v_2 = w_2$ .

Figure 1:  $S_9 \square H_4$ .

most  $k$  internal vertices, then  $G'$  is a  $(\leq k)$ -subdivision of  $G$ . Blankenship and Oporowski [4] conjectured that the stack-number of  $(\leq k)$ -subdivisions ( $k$  fixed) is not much less than the stack-number of the original graph. More precisely:

**Conjecture 1** ([4]). *There exists a function  $f$  such that for every graph  $G$  and integer  $k$ , if  $G'$  is any  $(\leq k)$ -subdivision of  $G$ , then  $\text{sn}(G) \leq f(\text{sn}(G'), k)$ .*

Dujmović and Wood [8] established a connection between this conjecture and the question of whether stack-number is bounded by queue-number. In particular, they showed that if Conjecture 1 is true, then stack-number is bounded by queue-number. Since Theorem 1 shows that stack-number is not bounded by queue-number, Conjecture 1 is false. The proof of Dujmović and Wood [8] is based on the following key lemma: every graph  $G$  has a 3-stack subdivision with  $1 + 2\lceil \log_2 \text{qn}(G) \rceil$  division vertices per edge. Applying this result to the graph  $G = S_b \square H_n$  in Theorem 1, the 5-subdivision of  $S_b \square H_n$  has a 3-stack layout. If Conjecture 1 was true, then  $\text{sn}(S_b \square H_n) \leq f(3, 5)$ , contradicting Theorem 1.

### Is Queue-number Bounded by Stack-Number?

It remains open whether queues are more powerful than stacks; that is, whether queue-number is bounded by stack-number. Several results are known about this problem. Heath et al. [12] showed that every 1-stack graph has a 2-queue layout. Dujmović et al. [6] showed that planar graphs have bounded queue-number. (Note that graph products also feature heavily in this proof.) Since 2-stack graphs are planar, this implies that 2-stack graphs have bounded queue-number. It is open whether 3-stack graphs have bounded queue-number. In fact, the case of three stacks is as hard as the general question. Dujmović and Wood [8] proved that queue-number is bounded by stack-number if and only if 3-stack graphs have bounded queue-number. Moreover, if this is true then stack-number is bounded by a polynomial function of queue-number.

## 2 Stack and Queue Layouts of Cartesian Products

First we prove that  $\text{qn}(S_b \square H_n) \leq 4$ , as claimed in Theorem 1. We need the following definition due to Wood [17]. A queue layout  $(\varphi, <)$  is *strict* if for every vertex  $u \in V(G)$  and

Add discussion of result of Bernhart and Kainen [2]:  
 $\text{sn}(G \square H) \leq \text{sn}(G) +$

---

for all neighbours  $v, w \in N_G(u)$ , if  $u < v, w$  or  $v, w < u$ , then  $\varphi(uv) \neq \varphi(uw)$ . Let  $\text{sqn}(G)$  be the minimum integer  $k$  such that  $G$  has a strict  $k$ -queue layout. To see that  $\text{sqn}(H_n) \leq 3$ , order the vertices row-by-row and then left-to-right within a row, with vertical edges in one queue, horizontal edges in one queue, and diagonal edges in another queue. Wood [17] proved that  $\text{qn}(G \square H) \leq \text{qn}(G) + \text{sqn}(H)$  for all graphs  $G$  and  $H$ . Of course,  $S_b$  has a 1-queue layout (since no two edges are nested for any vertex-ordering). Thus  $\text{qn}(S_b \square H_n) \leq 4$ .

### 3 The Main Proof

We now turn to the proof of our main result, the lower bound on  $\text{sn}(G)$ , where  $G := S_b \square H_n$ . Consider a hypothetical  $s$ -stack layout  $(\varphi, <)$  of  $G$  where  $n$  and  $b$  are chosen sufficiently large compared to  $s$  as detailed below. We begin with three lemmata that, for sufficiently large  $b$ , provide a large subgraph  $S_d$  of  $S_b$  for which the induced stack layout of  $S_d \square H_n$  is highly structured.

For each node  $v$  of  $S_b$ , define  $\pi_v$  as the permutation of  $\{1, \dots, n\}^2$  in which  $(x_1, y_1)$  appears before  $(x_2, y_2)$  if and only if  $(v, (x_1, y_1)) < (v, (x_2, y_2))$ . The following lemma is an immediate consequence of the Pigeonhole Principle:

**Lemma 1.** *There exists a permutation  $\pi$  of  $\{1, \dots, n\}^2$  and a set  $L_1$  of leaves of  $S_b$  of size  $a \geq b/(n^2)!$  such that  $\pi_v = \pi$  for each  $v \in L_1$ .*

For each leaf  $v$  in  $L_1$ , let  $\varphi_v$  be the edge colouring of  $H_n$  defined by  $\varphi_v(x, y) := \varphi(v, (x, y))$ . Since  $H_n$  has maximum degree 6 and is not 6-regular, it has fewer than  $3n^2$  edges. Therefore there are fewer than  $s^{3n^2}$  edge colourings of  $H_n$  using  $s$  colours. Another application of the Pigeonhole Principle proves the following:

**Lemma 2.** *There exists a subset  $L_2 \subseteq L_1$  of size  $c \geq a/s^{3n^2}$  and an edge colouring  $\phi : E(H_n) \rightarrow \{1, \dots, s\}$  such that  $\varphi_v = \phi$  for each  $v \in L_2$ .*

Let  $S_c$  be the subgraph of  $S_b$  induced by  $L_2 \cup \{r\}$ . The preceding two lemmata ensure that, for distinct leaves  $v$  and  $w$  of  $S_c$ , the stack layouts of the isomorphic graphs  $G[\{(v, p) : p \in V(H_n)\}]$  and  $G[\{(w, p) : p \in V(H_n)\}]$  are identical. The next lemma is a statement about the relationships between the stack layouts of  $G[\{(v, p) : v \in V(S_c)\}]$  and  $G[\{(v, q) : v \in V(S_c)\}]$  for distinct  $p, q \in V(H_n)$ . It does not assert that these two layouts are identical but it does state that they fall into one of two categories.

**Lemma 3.** *There exists a sequence  $L_3 := u_1, \dots, u_d$  with  $\{u_1, \dots, u_d\} \subseteq L_2$  of length  $d \geq c^{1/2^{n^2-1}}$  such that, for each  $p \in V(H_n)$ , either  $(u_1, p) < (u_2, p) < \dots < (u_d, p)$  or  $(u_1, p) > (u_2, p) > \dots > (u_d, p)$ .*

*Proof.* Let  $p_1, \dots, p_{n^2}$  denote the vertices of  $H_n$  in any order. Begin with the sequence  $S_1 := v_{1,1}, \dots, v_{1,c}$  that contains all  $c$  elements of  $L_2$  ordered so that  $(v_{1,1}, p_1) < \dots < (v_{1,c}, p_1)$ . For each  $i \in \{2, \dots, n^2\}$ , the Erdős-Szekeres Theorem [10] implies that  $S_{i-1}$  contains a subsequence  $S_i := v_{i,1}, \dots, v_{i,|S_i|}$  of length  $|S_i| \geq \sqrt{|S_{i-1}|}$  such that  $(v_{i,1}, p_i) < \dots < (v_{i,d_i}, p_i)$  or  $(v_{i,1}, p_i) > \dots > (v_{i,d_i}, p_i)$ . It is straightforward to verify by induction on  $i$  that  $d_i \geq c^{1/2^{i-1}}$  resulting in a final sequence  $S_{n^2} =: L_3$  of length at least  $c^{1/2^{n^2-1}}$ .  $\square$

Figure 2: The sets  $Z_{n,v_1}, \dots, Z_{n,v_{d'}}$  ( $n = 4, d' = 5$ ).

For the rest of the proof we will work with the star  $S_d$  whose leaves are  $u_1, \dots, u_d$  described in Lemma 3. Consider the (improper) vertex colouring of  $H_n$  obtained by colouring each vertex  $p \in V(H_n)$  red if  $(u_1, p) < \dots < (u_d, p)$  and colouring  $p$  blue if  $(u_1, p) > \dots > (u_d, p)$ . We need the following famous Hex Lemma [11].

**Lemma 4** ([11]). *Every red–blue vertex colouring of the graph  $H_n$  contains an  $n$ -vertex path  $R$  consisting entirely of red vertices or entirely of blue vertices.*

Without loss of generality, assume that the path  $R := p_1, \dots, p_n$  defined by Lemma 4 (with the above-defined colouring) consists entirely of red vertices, so that  $(u_1, p_j) < \dots < (u_d, p_j)$  for each  $j \in \{1, \dots, n\}$ . Recall that  $(\varphi, <)$  is a hypothetical  $s$ -stack layout of  $G$  and therefore it is also an  $s$ -stack layout of the subgraph  $X := S_d \square R$ . In particular, there is no set of greater than  $s$  pairwise crossing edges in  $X$ . The following result finishes the proof by showing that such a set exists when  $n > 2s$  and  $d \geq (s+1)2^n$  (which is implied if  $n = 2s+1$  and  $b \geq (n^2)!s^{3n^2}((s+1)2^n)^{2^{n-1}}$ ).

**Lemma 5.** *The graph  $X$  contains a set of edges of size at least  $\min\{\lfloor d/2^n \rfloor, \lceil n/2 \rceil\}$  that are pairwise crossing with respect to  $<$ .*

*Proof.* We will define sets  $A_1 \supseteq \dots \supseteq A_n$  of leaves of  $S_d$  so that each  $A_i$  satisfies the following conditions:

- (C1)  $A_i$  contains  $d_i \geq d/2^{i-1}$  leaves of  $S_d$ .
- (C2) Each leaf  $v \in A_i$  defines an  $i$ -element vertex set  $Z_{i,v} := \{(v, p_j) : j \in \{1, \dots, i\}\}$ . For any distinct  $v, w \in A_i$ , the sets  $Z_{i,v}$  and  $Z_{i,w}$  are separated with respect to  $<$ ; that is,  $Z_{i,v} < Z_{i,w}$  or  $Z_{i,v} > Z_{i,w}$ .

Before defining  $A_1, \dots, A_n$  we first show how the existence of the set  $A_n$  implies the lemma. To avoid triple-subscripts, let  $d' := d_n \geq d/2^{n-1}$ . The set  $A_n$  defines vertex sets  $Z_{n,v_1} < \dots < Z_{n,v_{d'}}$ . Refer to Figure 2. Recall that  $r$  is the root of  $S_b$  so it is adjacent to each of  $v_1, \dots, v_{d'}$  in  $S_d$ . Therefore, for each  $j \in \{1, \dots, n\}$  and each  $i \in \{1, \dots, d'\}$ , the edge  $(r, p_j)(v_i, p_j)$  is in  $X$ . Therefore,  $(r, p_j)$  is adjacent to an element of each of  $Z_{n,v_1}, \dots, Z_{n,v_{d'}}$ .

Figure 3: The two cases in the proof of Lemma 5.

Since  $Z_{n,v_1}, \dots, Z_{n,v_{d'}}$  are separated with respect to  $<$ , when viewed from afar, this situation looks like a complete bipartite graph  $K_{n,d'}$  with the root vertices  $L := \{(r, p_j) : j \in \{1, \dots, n\}\}$  in one part and the groups  $R := Z_{n,v_1} \cup \dots \cup Z_{n,v_{d'}}$  in the other part. Any linear ordering of  $K_{n,d'}$  has a large set of pairwise crossing edges so, intuitively, the induced subgraph  $X[L \cup R]$  should also have a large set of pairwise crossing edges. We can formalize this as follows: Label the vertices in  $L$  as  $r_1, \dots, r_n$  so that  $r_1 < \dots < r_n$ . Then at least one of the following two cases applies (see Figure 3):

1.  $Z_{n, \lceil d'/2 \rceil} < r_{\lceil n/2 \rceil}$  in which case the graph between  $r_{\lceil n/2 \rceil}, \dots, r_n$  and  $Z_{n,1}, \dots, Z_{n, \lceil d'/2 \rceil}$  has a set of at least  $\min\{\lceil d'/2 \rceil, \lceil n/2 \rceil\}$  pairwise-crossing edges.
2.  $r_{\lceil n/2 \rceil} < Z_{\lceil d'/2 \rceil + 1}$  in which case the graph between  $r_1, \dots, r_{\lceil n/2 \rceil}$  and  $Z_{\lceil d'/2 \rceil + 1}, \dots, Z_{d'}$  has a set of  $\min\{\lceil d'/2 \rceil, \lceil n/2 \rceil\}$  pairwise-crossing edges.

Since, by (C1),  $d' \geq d/2^{n-1}$ , either case results in a set of pairwise-crossing edges of size at least  $\min\{\lceil d/2^n \rceil, \lceil n/2 \rceil\}$ , as claimed.

All that remains is to define the sets  $A_1 \supseteq \dots \supseteq A_n$  that satisfy (C1) and (C2). Let  $A_1$  be the set of all the leaves of  $S_d$ . For each  $i \in \{2, \dots, n\}$ , the set  $A_i$  is defined as follows: Let  $Z_1, \dots, Z_{|A_{i-1}|}$  denote the sets  $Z_{i-1,v}$  for each  $v \in A_{i-1}$  ordered so that  $Z_1 < \dots < Z_r$ . By Property (C2), this is always possible. Label the vertices of  $A_{i-1}$  as  $v_1, \dots, v_{|A_{i-1}|}$  so that  $(v_1, p_{i-1}) < \dots < (v_r, p_{i-1})$ . (This is equivalent to naming them so that  $(v_j, p_{i-1}) \in Z_j$  for each  $j \in \{1, \dots, |A_{i-1}|\}$ .) Define the set  $A_i := \{v_{2k+1} : k \in \{0, \dots, \lfloor (|A_{i-1}| - 1)/2 \rfloor\}\} = \{v_j \in A_{i-1} : j \text{ is odd}\}$ . This completes the definition of  $A_1, \dots, A_n$ .

All that remains is to verify that  $A_i$  satisfies (C1) and (C2). We do this by induction on  $i$ . The base case  $i = 1$  is trivial so we assume from this point on that  $i \in \{2, \dots, n\}$ . To see that  $A_i$  satisfies (C1) just observe that  $|A_i| = \lceil |A_{i-1}|/2 \rceil \geq |A_{i-1}|/2 \geq d/2^{i-1}$ , where the final inequality follows by applying the inductive hypothesis  $|A_{i-1}| \geq d/2^{i-2}$ . All that remains is to show that  $A_i$  satisfies (C2).

For each  $j \in \{i-1, i\}$ , let  $H^j := \{(v, p_j) : v \in A_{i-1}\}$ . Recall that, for each  $v \in A_{i-1}$ , the edge  $e_v := (v, p_{i-1})(v, p_i)$  is in  $X$ . We have the following properties:

---

(P1) By Lemma 2,  $\varphi(e_v) = \phi(p_{i-1}p_i)$  for each  $v \in A_{i-1}$ .

(P2) Since  $p_{i-1}$  and  $p_i$  are both red,  $(v, p_{i-1}) < (w, p_{i-1})$  if and only if  $(v, p_i) < (w, p_i)$  for each  $v, w \in A_{i-1}$ .

(P3) By Lemma 1,  $(v, p_{i-1}) < (v, p_i)$  for every  $v \in A_{i-1}$  or  $(v, p_{i-1}) > (v, p_i)$  for every  $v \in A_{i-1}$ .

We claim that these three conditions imply that the vertex sets of  $H^{i-1}$  and  $H^i$  interleave perfectly with respect to  $<$ . More precisely:

**Claim 1.**  $(v_1, p_{i-1+t}) < (v_1, p_{i-t}) < (v_2, p_{i-1+t}) < (v_2, p_{i-t}) \cdots < (v_r, p_{i-1+t}) < (v_r, p_{i-t})$  for some  $t \in \{0, 1\}$ .

*Proof of Claim 1.* By (P3) we may assume, without loss of generality, that  $(v, p_{i-1}) < (v, p_i)$  for each  $v \in A_{i-1}$ , in which case we are trying to prove the claim for  $t = 0$ . Therefore, it is sufficient to show that  $(v_j, p_i) < (v_{j+1}, p_{i-1})$  for each  $j \in \{1, \dots, r-1\}$ . For the sake of contradiction, suppose  $(v_j, p_i) > (v_{j+1}, p_{i-1})$  for some  $j \in \{1, \dots, r-1\}$ . By the labelling of  $A_{i-1}$ ,  $(v_j, p_{i-1}) < (v_{j+1}, p_{i-1})$  so, by (P2),  $(v_j, p_i) < (v_{j+1}, p_i)$ . Therefore

$$(v_j, p_{i-1}) < (v_{j+1}, p_{i-1}) < (v_j, p_i) < (v_{j+1}, p_i) .$$

Therefore the edges  $e_{v_j} = (v_j, p_{i-1})(v_j, p_i)$  and  $e_{v_{j+1}} = (v_{j+1}, p_{i-1})(v_{j+1}, p_i)$  cross with respect to  $<$ . But this is a contradiction since, by (P1),  $\varphi(e_{v_j}) = \varphi(e_{v_{j+1}}) = \phi(p_{i-1}p_i)$ . This contradiction completes the proof of Claim 1.  $\square$

We now complete the proof that  $A_i$  satisfies (C2). Apply Claim 1 and assume without loss of generality that  $t = 0$ , so that

$$(v_1, p_{i-1}) < (v_1, p_i) < (v_2, p_{i-1}) < (v_2, p_i) \cdots < (v_r, p_{i-1}) < (v_r, p_i) .$$

For each  $j \in \{1, \dots, r-2\}$ , we have  $(v_{j+1}, p_{i-1}) \in Z_{j+1} < Z_{j+2}$ , so  $(v_j, p_i) < (v_{j+1}, p_{i-1}) < Z_{j+2}$ . Therefore  $Z_j \cup \{(v_j, p_i)\} < Z_{j+2}$ . By a symmetric argument,  $Z_j \cup \{(v_j, p_i)\} > Z_{j-2}$  for each  $j \in \{3, \dots, r\}$ . Finally, since  $(v_j, p_i) < (v_{j+2}, p_i)$  for each odd  $i \in \{1, \dots, r\}$ , we have  $Z_j \cup \{(v_j, p_i)\} < Z_{j+2} \cup \{(v_{j+2}, p_i)\}$  for each odd  $j \in \{1, \dots, r-2\}$ . Thus  $A_i$  satisfies (C2) since the sets  $Z_1 \cup \{(v_1, p_i)\}, Z_3 \cup \{(v_3, p_i)\}, \dots, Z_{2\lfloor (r-1)/2 \rfloor + 1} \cup \{(v_{2\lfloor (r-1)/2 \rfloor + 1}, p_i)\}$  are precisely the sets  $Z_{i,1}, \dots, Z_{i,d_i}$  determined by our choice of  $A_i$ .  $\square$

## 4 Open Problems

Recall that every 1-queue graph has a 2-stack layout [12] and we proved that there are 4-queue graphs with unbounded stack-number. The following questions remain open: Do 2-queue graphs have bounded stack-number? Do 3-queue graphs have bounded stack-number?

Given the role of cartesian products in our proof, it is natural to ask when is  $\text{sn}(G_1 \square G_2)$  bounded? Note that  $H_n$  is a subgraph of a planar Hamiltonian graphs (namely,  $H_{2n}$ ), so  $\text{sn}(H_n) \leq 2$ . So  $\text{sn}(G_1 \square G_2)$  can be unbounded even when  $G_1$  is a star and  $\text{sn}(G_2) \leq 2$ . Since  $\text{sn}(G_2) \leq 1$  if and only if  $G_2$  is outerplanar, the following question naturally arises: Is  $\text{sn}(S \square H)$  bounded for every star  $S$  and outerplanar graph  $H$  with bounded degree? Is  $\text{sn}(T \square H)$  bounded for every tree  $T$  and outerplanar graph  $H$  with bounded degree? The

---

assumption that  $H$  has bounded degree is needed since  $S_n \square S_n$  contain the 1-subdivision of  $K_{n,n}$ , which has unbounded stack-number [3].

MENTION RESULTS OF Pupyrev [16] about bipartite graphs.

Since  $H_n \subseteq P \boxtimes P$  where  $P$  is the  $n$ -vertex path, Theorem 1 implies that  $\text{sn}(S \boxtimes P \boxtimes P)$  is unbounded for stars  $S$  and paths  $P$ . It is easily seen that  $\text{sn}(S \boxtimes P)$  is bounded [16]. The following question naturally arises (independently asked by Pupyrev [16]): Is  $\text{sn}(T \boxtimes P)$  bounded for every tree  $T$  and path  $P$ ? We conjecture the answer is “no”.
